

Ligurian Speleological Delegation (Italy)

(Delegazione Speleologica Ligure, Italia)

Curated by: Roberto Chiesa

Almost 7% of Ligurian land is covered by carbonatic rocks (limestone, dolomite and marly limestones, flyschs). The caves are developed mainly in the Triassic limestones.

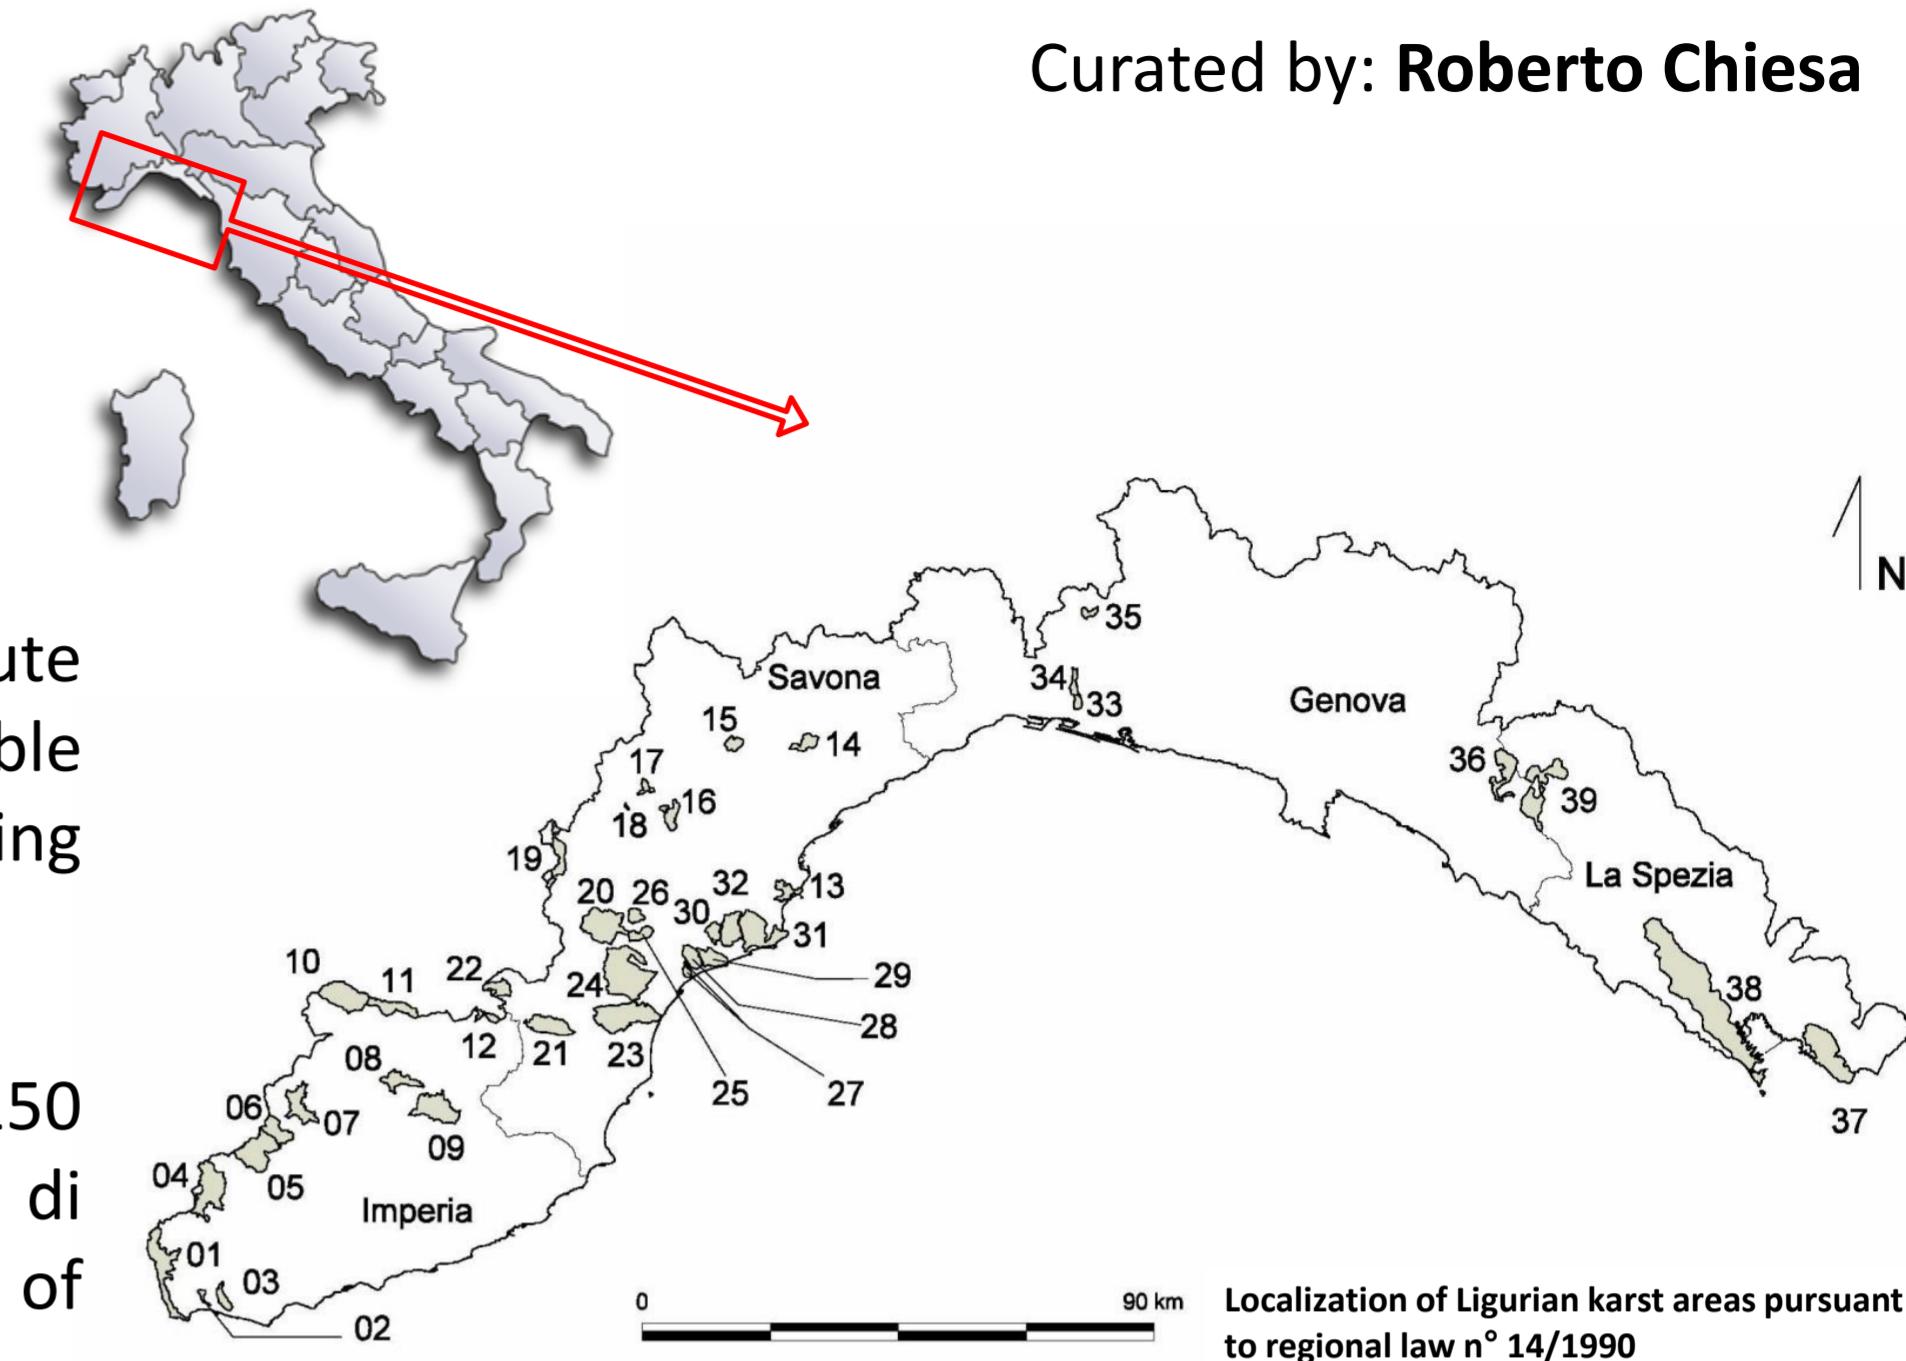

Karst waters

The Ligurian karst springs, are numerous but most of modest scope, they constitute an important source of water for Liguria, and in large part are captured for potable water purposes from small aqueducts supplying countries. Along the coast existing some underwater springs.

Except for rare and isolated cases there is impaired by pollution sources.

The *Sorgenti delle Dotte* (SV) are greater source in Liguria with approximately 150 l/s. The major hydro-karst systems are in the province of Savona (Buranco di Bardinetto-Balbiseolo-Buranco Ramiun; Pollera-Buio) and in the province of Imperia (Rugli cave).
